

Machine Learning with  
Perceptrons

# Machine Learning

Using statistical methods to make computers “learn” to do tasks when given example data. The methods improve the more example data is given.

# Some Vocab

## Classification

- Taking unknown input and assigning it to one or more known classes of data
- What ML is trying to do most of the time

## Feature

- A subset of a data point with all the “good” data

## Training

- Giving the ML algorithm example data to improve the classifier

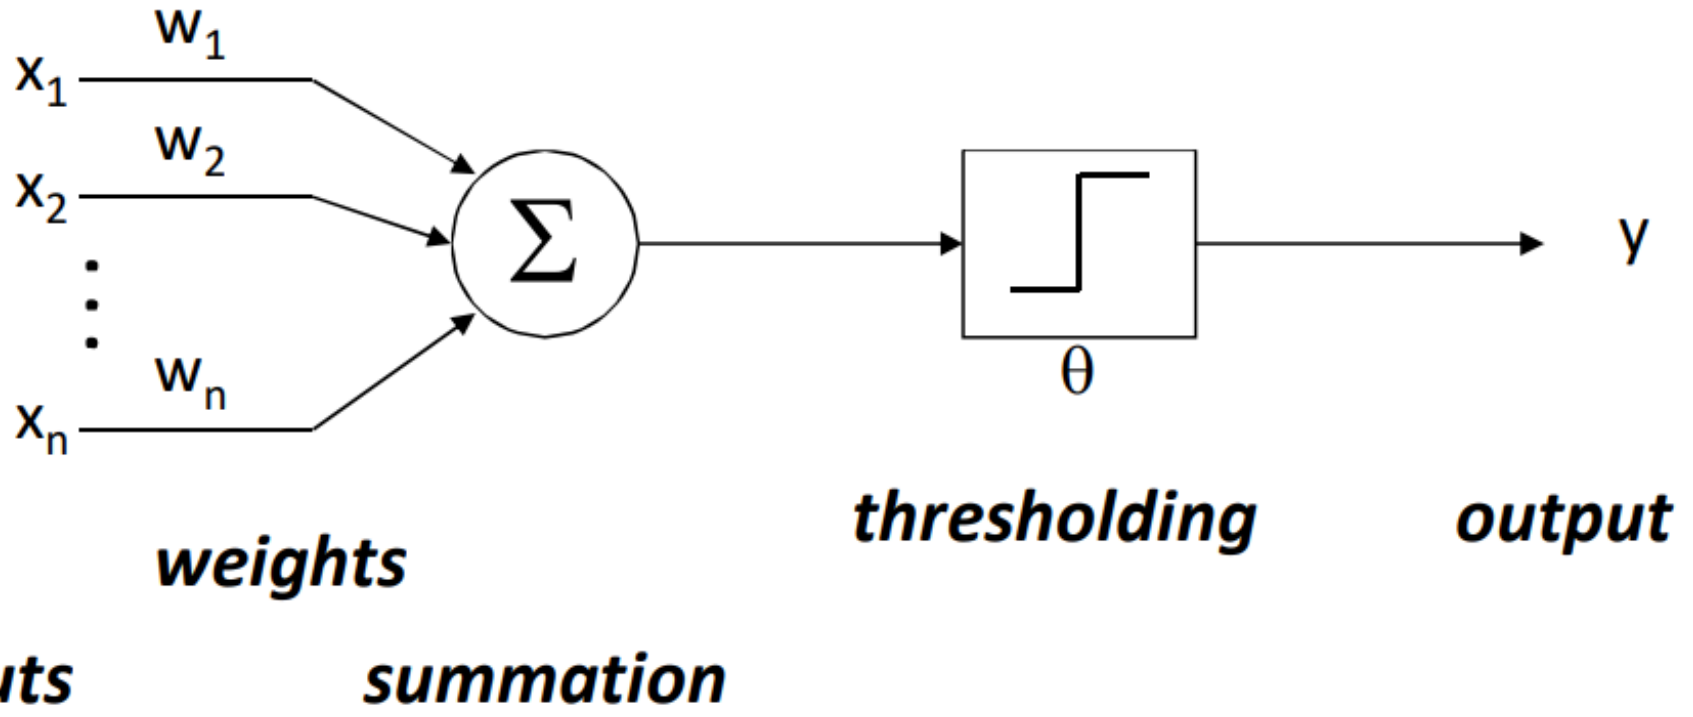

## Testing

- Using different data from training to assess the classifier

# + Perceptrons

- Attempt to mimic biological neurons
- Multiple inputs summed together -> single binary output
- Mathematically, actually pretty simple
- Can be stacked to increase complexity
  - Leads to things like *neural* networks and deep learning

$$y = \begin{cases} 1 & \text{if } \sum w_i x_i \geq \theta; \\ 0, & \text{otherwise.} \end{cases}$$

# Letter Example

Weight Vector

1	1	1	1
1	-1	-1	1
1	1	1	1
1	-1	-1	1

$$\Theta = 11.5$$

What will this perceptron output for each of these two inputs?

Test Data 1

1	1	1	1
1	0	0	1
1	1	1	1
1	0	0	1

Test Data 2

1	0	0	1
1	1	1	1
1	0	0	1
1	0	0	1

# Training the Perceptron

- Get a whole bunch of negative and positive examples  $\mathbf{X}$
- Create arbitrary initial classifier
  - $\mathbf{w}_0 = (0,0,0,\dots)$
  - $\Theta_0 = 1$
- Create constant to determine how “important” each new data point is
  - $c = 1$  (to keep it simple)

# + Training Algorithm

Classify  $X_k$  with  $w_k$  and  $\Theta_k$

Was it correct?

Move on to the next one

If not

Was it a false negative?

$$w_{k+1} = w_k + c * X_k \quad \text{and} \quad \Theta_{k+1} = \Theta_k - c$$

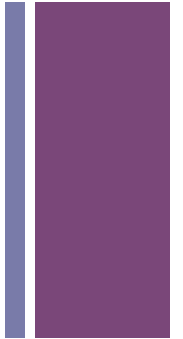

Was it a false positive?

$$w_{k+1} = w_k - c * X_k \quad \text{and} \quad \Theta_{k+1} = \Theta_k + c$$

Repeat the above until the classifier stops being wrong on any training data

# + Pseudocode

```
while (not converged)
  for (xk in trainingData)
    output = xk * wk
    if (output is false-negative)
      wk = wk + c*xk
      threshold = threshold - c
    else if (output is false-positive)
      wk = wk - c*xk
      threshold = threshold + c
```

# + Convergence Issues

- Classifier won't always converge
- Linear Separability

$$X^+ = \{ (0, 1), (1, 0) \}$$

$$X^- = \{ (0, 0), (1, 1) \}$$

$$X = X^+ \cup X^-$$

# + Solution: Add More Perceptrons!

# Let's Make and Train a Writing Classifier

- Get a (REAL) dataset of drawn numbers
  - <https://archive.ics.uci.edu/ml/datasets/Optical+Recognition+of+Handwritten+Digits>
  - Get the “optdigits.tra” file
- Get the skeleton code from the class website
- We're writing this in R
  - But I've done most of the syntax work for you

# + Very Brief R Intro

- Statistical programming language
- Good for math and creating data visualizations
- Free!
- Can program in a console like Unix
  - Or write scripts like most programming languages
- Assignment operation looks like “variable <- value”

# + More Things to Try

- See if you can figure out what the rest of the perceptron code is doing
  - I've commented most of it
- Alter the code to work with a different dataset
  - You will probably have to change some numbers at least
- Practice more things in R
